

*OnRISC: The watchdog timer doesn't reboot the system if the activating application was aborted.*

The WDT (WatchDog Timer) driver provides a special option called "Disable watchdog shutdown on close" to prevent stopping the timer on WDT descriptor close. This is a compile-time option. It is deactivated by default, so you have to build your own kernel if you need it.

`make menuconfig`

activate the option as shown below, and recompile the kernel.
